Q) Develop a C program that generates the histogram (frequency count of unique characters in the input text) using multiple threads (thread numbers to match with unique character count) , each thread performing the counting for that respective character. Compare the efficiency of the threaded version over its equivalent serial version.

sol)

CODE :

```
#include <stdio.h>
#include <stdlib.h>
#include <ctype.h>
#include <sys/wait.h>
#include <sys/mman.h>
#include <unistd.h>
#include <pthread.h>
#include <time.h>
```

```
int c;
int *charCount;
FILE *file;
```

```
FILE *openFile(char *filename) // open a file in read mode and return the
pointer
```

```

{
    FILE *file;
    file = fopen(filename, "r");

    if (!file)
    {
        printf("Error!\n");
        return NULL;
    }

    return file;
}

void *runner(void *param)
{
    int i = *((int *)param);
    while ((c = tolower(fgetc(file))) != EOF)
    {
        if (i == 26 && (c < 97 || c > 122))
            charCount[c]++; // Count other char
        else if (c == i + 97)
            charCount[i + 97] += 1; // Count letters
    }

    pthread_exit(0);
}

int main(int argc, char *argv[]) //command line arguments
{

    if (argc != 2)
    {
        printf("Syntax: ./a.out <filename>\n");
        return 1;
    }

```

```

char *filename = argv[1];

if ((file = openFile(filename)) == NULL)
return 1;

pthread_t tid;
pthread_attr_t attr;

charCount = mmap(NULL, 128 * sizeof(*charCount), PROT_WRITE,
MAP_SHARED | MAP_ANONYMOUS, -1, 0);
for (int i = 0; i < 27; i++)
{

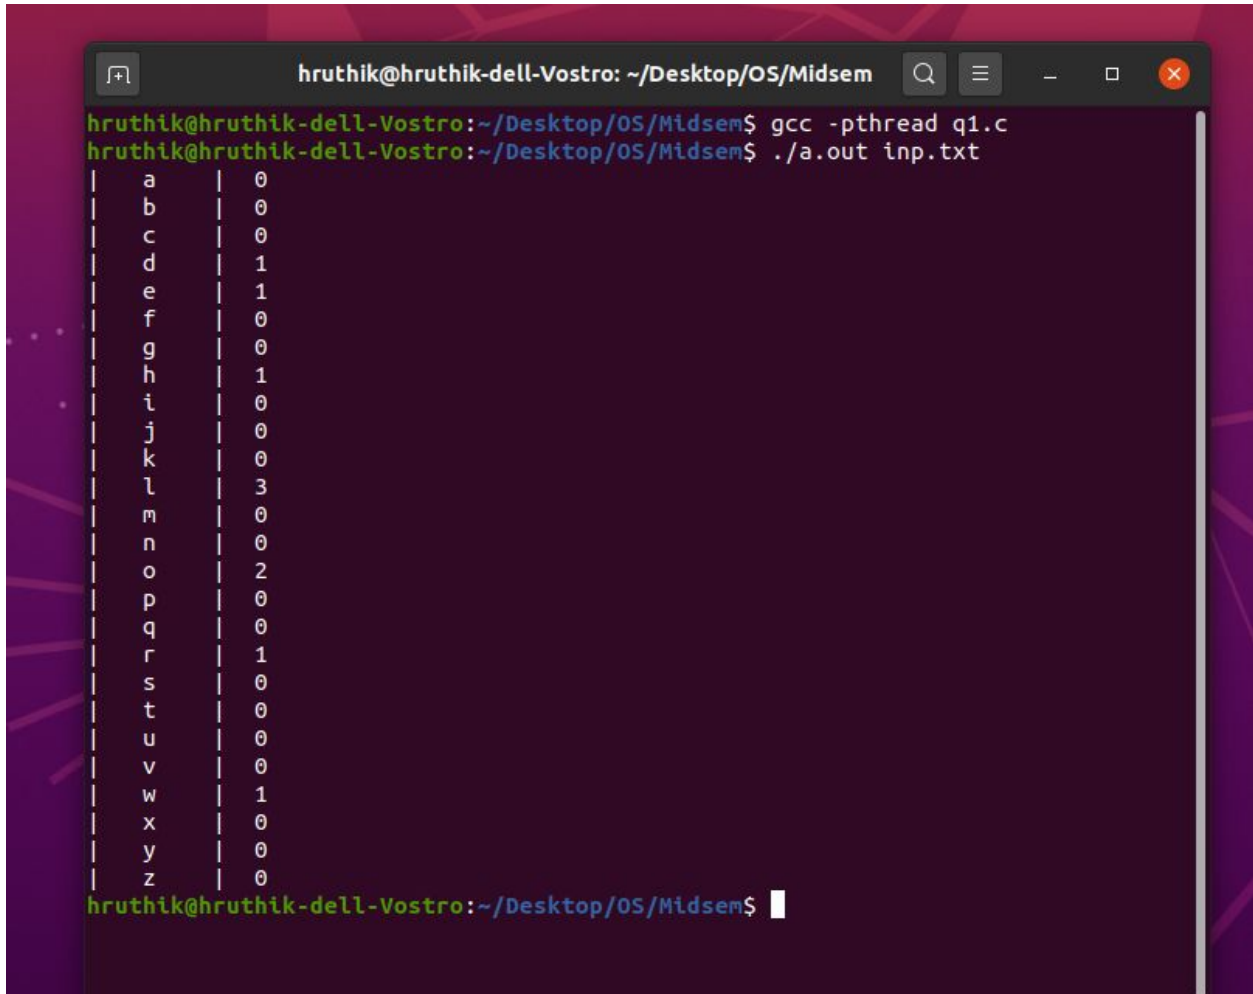

file = openFile(filename);
int *arg = malloc(sizeof(*arg));
*arg = i;
rewind(file);
pthread_attr_init(&attr);
pthread_create(&tid, &attr, runner, arg);
pthread_join(tid, NULL);
}
for (int i = 97; i < 123; i++)
{
printf("|  %c      | %0d ", i, charCount[i]);
printf("\n");
}

if (fclose(file) != 0)
{
printf("Error closing file!\n");
return 1;
}

return 0;
}

```

OUTPUT :

```
hruthik@hruthik-dell-Vostro: ~/Desktop/OS/Midsem$ gcc -pthread q1.c
hruthik@hruthik-dell-Vostro: ~/Desktop/OS/Midsem$ ./a.out inp.txt
| a | 0 |
| b | 0 |
| c | 0 |
| d | 1 |
| e | 1 |
| f | 0 |
| g | 0 |
| h | 1 |
| i | 0 |
| j | 0 |
| k | 0 |
| l | 3 |
| m | 0 |
| n | 0 |
| o | 2 |
| p | 0 |
| q | 0 |
| r | 1 |
| s | 0 |
| t | 0 |
| u | 0 |
| v | 0 |
| w | 1 |
| x | 0 |
| y | 0 |
| z | 0 |
hruthik@hruthik-dell-Vostro: ~/Desktop/OS/Midsem$
```

The terminal window shows the execution of a C program. The first command is `gcc -pthread q1.c`, which compiles the program. The second command is `./a.out inp.txt`, which runs the program on the input file `inp.txt`. The output is a table showing the count of each character in the input text. The characters are listed in the first column, and their counts are in the second column. The counts are: a:0, b:0, c:0, d:1, e:1, f:0, g:0, h:1, i:0, j:0, k:0, l:3, m:0, n:0, o:2, p:0, q:0, r:1, s:0, t:0, u:0, v:0, w:1, x:0, y:0, z:0.

THE TEXT USED IN THE CODE IS : “helloworld”

The above code is the multi threading version of Histogram generator to count the occurrence of various characters in a given text.

EFFICIENCY :

The time complexity of the Histogram is :

Time Complexity: $O(n)$,
where n is the number of characters in the string.

AMDAHL'S LAW :

In general terms, Amdahl's Law states that in parallelization, if P is the proportion of a system or program that can be made parallel, and $1-P$ is the proportion that remains serial, then the maximum speedup $S(N)$ that can be achieved using N processors is: $S(N) = 1 / ((1-P) + (P/N))$. As N grows the speedup tends to $1/(1-P)$.

The Amdahl's Law calculator computes the speedup of the execution of a task based on the speed up factor (s) of the improvable portion of the task and the proportion (p) of the task that can be improved.

The Math / Science

1. v = speedup factor.
 2. P = portion of the task accelerated.
 3. S = speedup for the portion.
- If P_e is the performance for entire task using the enhancement when possible, P_w is the performance for entire task without using the enhancement, E_w is the execution time for entire task without using the enhancement and E_e is the execution time for entire task using the enhancement when possible then,

$$\text{Speedup} = P_e / P_w$$

Or

$$\text{Speedup} = E_w/E_e$$

$$\begin{aligned} \text{Overall Speedup} &= \frac{\text{Old execution time}}{\text{New execution time}} \\ &= \frac{1}{\left((1 - \text{Fraction}_{\text{enhanced}}) + \frac{\text{Fraction}_{\text{enhanced}}}{\text{Speedup}_{\text{enhanced}}} \right)} \end{aligned}$$

Let's take an example, if the part that can be improved is 30% of the overall system and its performance can be doubled for a system, then –

$$\text{Speedup}_{\text{MAX}} = 1/((1-0.30)+(0.30/2))$$

$$= 1.18$$

Now, in another example, if the part that can be improved is 70% of the overall system and its performance can be doubled for a system, then –

$$\text{Speedup}_{\text{MAX}} = 1/((1-0.70)+(0.70/2))$$

$$= 1.54$$

So, we can see, if 1-p can't be improved, the overall performance of the system cannot be improved so much. So, if 1-p is 1/2, then speed cannot go beyond that, no matter how many processors are used.

- Multicore programming is most commonly used in signal processing and plant-control systems. In signal processing, one can have a concurrent system that processes multiple frames in parallel. The controller and the plant can execute as two separate tasks, in plant-control systems.

- Multicore programming helps to split the system into multiple parallel tasks, which run simultaneously, speeding up the overall execution time.

Serial code for Histogram :

```
#include <bits/stdc++.h>
```

```
using namespace std;
```

```
#define SIZE 26
```

```
void printCharWithFreq(string str)
```

```
{
```

```
    // size of the string 'str'
```

```
    int n = str.size();
```

```
    // 'freq[]' implemented as hash table
```

```
    int freq[SIZE];
```

```
    // initialize all elements of freq[] to 0
```

```
    memset(freq, 0, sizeof(freq));
```

```
    // accumulate frequency of each character in 'str'
```

```
    for (int i = 0; i < n; i++)
```

```
        freq[str[i] - 'a']++;
```

```
// traverse 'str' from left to right
for (int i = 0; i < n; i++) {

    // if frequency of character str[i] is not
    // equal to 0
    if (freq[str[i] - 'a'] != 0) {

        // print the character along with its
        // frequency
        cout << str[i] << freq[str[i] - 'a'] << " ";

        // update frequency of str[i] to 0 so
        // that the same character is not printed
        // again
        freq[str[i] - 'a'] = 0;
    }
}

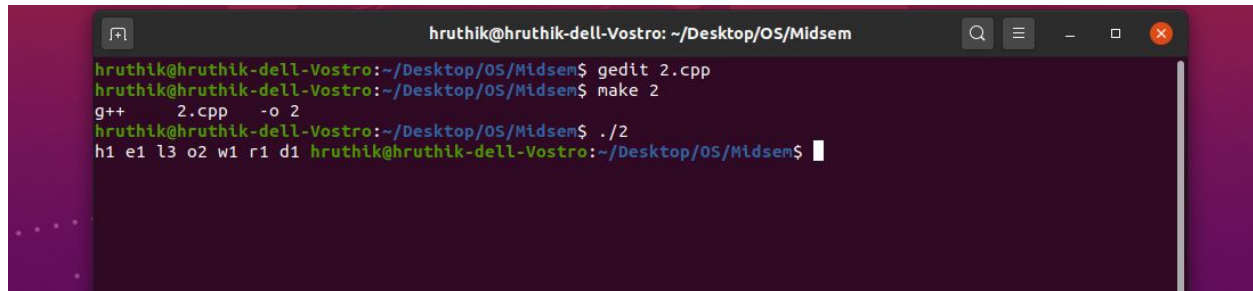

int main()
{
    string str = "helloworld";

    printCharWithFreq(str);
}
```

```
    return 0;  
}
```

OUTPUT :

A terminal window titled 'hruthik@hruthik-dell-Vostro: ~/Desktop/OS/Midsem' with standard window controls. The terminal shows the following commands and output:

```
hruthik@hruthik-dell-Vostro:~/Desktop/OS/Midsem$ gedit 2.cpp  
hruthik@hruthik-dell-Vostro:~/Desktop/OS/Midsem$ make 2  
g++ 2.cpp -o 2  
hruthik@hruthik-dell-Vostro:~/Desktop/OS/Midsem$ ./2  
h1 e1 l3 o2 w1 r1 d1 hruthik@hruthik-dell-Vostro:~/Desktop/OS/Midsem$
```

Advantages of Thread

- Threads minimize the context switching time.
- Use of threads provides concurrency within a process.
- Efficient communication.
- It is more economical to create and context switch threads.
- Threads allow utilization of multiprocessor architectures to a greater scale and efficiency.

NOTE :

Therefore the Multi threading version of histogram is more efficient than the serial version of the histogram.
